Abstract

**Purpose:** To evaluate the effect of phacoemulsification and posterior chamber intraocular lens (PCIOL) implantation on intraocular pressure (IOP) in eyes with chronic angle-closure glaucoma.

**Methods:** Twenty-two patients with chronic angle-closure glaucoma (CACG) and visually significant cataract were included in our study. All underwent phacoemulsification and PCIOL implantation. IOP, depth of angle, visual acuity, and the number of antiglaucoma medications were recorded preoperatively and one day, one week, one month, two months, and six months postoperatively.

**Results:** The mean age was 71.04±6.55 years and there were 8 males (36.4%) and 14 females (63.6%). The mean IOP was 19.54±1.49 mm Hg preoperatively and 16.04±1.49 mm Hg six months postoperatively. The mean number of antiglaucoma medications was 2 preoperatively and 0.18±0.50 at final follow-up. The mean preoperative LogMAR visual acuity was 1.00 and 0.3 at final follow-up (P <0.005).

**Conclusion:** When chronic angle-closure glaucoma is associated with visually significant cataract, phacoemulsification and PCIOL implantation alone can significantly reduce intraocular pressure.

**Keywords:** Chronic Angle-Closure Glaucoma, Phacoemulsification, Intraocular Pressure
Many studies have shown that cataract extraction and PCIOL insertion decreases IOP in eyes with glaucoma and visually significant cataract.

Although the effect depends considerably on the type of glaucoma it can be significant in CACG patients.

In these studies, the IOP reduction was attributed to significant widening of the anterior chamber angle.

It is known that CACG patients have thicker lenses than normal eyes which is significantly positioned anteriorly. These two mechanisms may completely account for the shallow anterior chamber and indirectly narrow angle in these patients.

Therefore it seems reasonable that cataract surgery can improve IOP control in eyes with CACG.

**Methods**

We studied 22 eyes of 22 patients with CACG who underwent phacoemulsification and PCIOL implantation from 2003 to 2005 in Farabi eye hospital (Table 1).

Inclusion criterion was CACG with visually significant cataract. Exclusion criteria were: IOP>30, Pseudoexfoliation (PEX) glaucoma, any previous intraocular surgery except peripheral iridectomy, Cup to disc (C/D) ratio >0.7, neovascularization of iris (NVI), and phacodonesis.

All eyes underwent phacoemulsification and PCIOL insertion. Briefly, a 3.2 mm clear corneal incision was made temporally. After viscoelastic injection and capsulorhexis of average 5 mm size, hydrodissection and hydrodelineation were performed and then phacoemulsification was done and a single-piece Alcon PCIOL (SA60) was implanted in the bag.

All patients were followed for 6 months. IOP was measured by Goldman tonometer before surgery and after surgery at intervals of 1, 7, 30, 60, and 180 days.

Pre- and postoperative best corrected visual acuity, angle grading (by gonioscopy), and anterior chamber depth with Spaeth method were assessed and medications were recorded. Also C/D ratio was recorded pre- and postoperatively with slit-lamp and +90 D lens.

Failure was defined as: IOP≥21 in two visits one week apart or need for more antiglaucoma medication than before surgery.

Our study was interventional case series. Statistical analysis was performed with paired t-test. P value less than 0.05 was considered significant.

**Results**

There were 8 males (36.4%) and 14 females (63.6%) in our study.

The mean age was 71.04±6.55 years. Follow-up period was 6 months.

All surgeries were completed with no major complication. 9 patients (40.9%) had hypertension, 6 (27.3%) ischemic heart disease, and 7 (31.8%) diabetes mellitus.

All eyes had laser peripheral iridotomy. 5 eyes (22.7%) had glaucomafleken.

The mean preoperative medications was 2 drug and decreased to 0.18 postoperatively (P<0.001).

Mean IOP was 19.54±2.9 mm Hg before surgery and 16.1±3.2 mm Hg (P<0.05), 15.63±2.3 (P<0.05), 16.13±1.6 (P<0.05), 16.68±3.3 (P<0.05) and 16.04±1.04 (P<0.05) at 1, 7, 30, 60 and 180 days respectively after surgery (Table 2).

Anterior chamber depth after surgery was wider than before operation (Spaeth classification average one degree).

Mean LogMAR visual acuity was 1.00 before cataract extraction and 0.3 at final follow-up. Visual acuity improved in all eyes.
after surgery. No additional surgery or laser procedure was needed in any of the cases during the study period.

**Discussion**

There are 3 treatment options for patients with CACG and cataract: cataract surgery alone, combined surgery, and glaucoma surgery alone followed by cataract extraction. Cataract surgery in these patients poses some unique difficulties. The anterior chamber is characteristically shallow and also the phaco surgeon applies forces through ultrasonic power closer to the corneal endothelium leading to endothelial loss and corneal edema. In view of all these inherent difficulties of performing phaco in these eyes, we had no major complications. In all eyes the anterior chamber depth increased after surgery and there was some angle widening.

It has been reported that cataract surgery alone decreases IOP to some extent in glaucoma patients. The degree of IOP reduction differs depending on the type of glaucoma. Ming Zhi et al reported a 9 mm Hg drop in first day postoperative IOP in acute primary angle-closure glaucoma.11

Hayashi et al reported a 5 mm Hg drop in mean IOP one month postoperatively in ACG patients3 and Lai et al showed a 4 mm Hg drop in postoperative IOP in CACG patients.2

In our study cataract extraction significantly decreased IOP in eyes with chronic angle-closure glaucoma and this decrease continued for up to 6 months. In this study, mean decrease in IOP after cataract surgery was 3.5±2.7 mm Hg which is comparable to previous reports. Also the number of glaucoma medications decreased after cataract extraction.

Hayashi et al showed significant increase in angle width after lens extraction in CACG patients which was comparable with our study.

Visual acuity was significantly improved after cataract surgery. No eye developed serious complication or had impaired visual acuity.

Our study had some limitations. We did not have ultrasound biomicroscopy to compare preoperative and postoperative ultrasonic findings of the angle. The number of our patients was also limited.

**Conclusion**

Phacoemulsification and PCIOL implantation significantly decreases IOP and the number of antiglaucoma medications in CACG patients. Furthermore if cataract extraction fails to control IOP, subsequent filtering surgery can be performed.
